Abstract

In non-word repetition (NWR) studies, participants are presented auditorily with an item that is phonologically legal but lexically meaningless in their language, and asked to repeat this item as closely as possible. NWR scores are thought to reflect some aspects of phonological 10 development, saliently a perception-production loop supporting flexible production patterns. In 11 this study, we report on NWR results among children (N = 40, aged 3–10 years) learning Yélî 12 Dnye, an isolate spoken on Rossel Island in Papua New Guinea. Results make three 13 contributions that are specific, and a fourth that is general. First, we found that non-word items 14 containing typologically frequent sounds are repeated without changes more often that 15 non-words containing typologically rare sounds, above and beyond any within-language 16 frequency effects. Second, we documented rather weak effects of item length. Third, we found 17 that age has a strong correlation with NWR scores, whereas there are weak correlations with 18 child sex, maternal education, and birth order. Fourth, we weave our results with those of others

to serve the general goal of reflecting on how NWR scores can be compared across participants,

universally structuring variation in phonological development at a global and individual level.

Non-word repetition in children learning Yélî Dnye

7 Introduction

26

Children's perception and production of phonetic and phonological units continues 28 developing well beyond the first year of life, even extending into middle childhood (e.g., Hazan & Barrett, 2000; Rumsey, 2017). Much of the evidence for later phonological development comes from non-word repetition (NWR) tasks. In a the present study, we use NWR to 31 investigate the phonological development of children learning Yélî Dnye, an isolate language 32 spoken in Papua New Guinea (PNG), which has a large and unusually dense phonological 33 inventory. This allows us to contribute data at the intersection of language typology, language acquisition, and individual variation, as presented in more detail below. 35 What is NWR?. In a basic NWR task, participants hear a short the participant listens to a 36 production of a word-like formthat is phonologically legal but lexically meaningless, such as /bilik/, and then repeats back what they heard without changing any phonological feature that is contrastive in the language(s) they are learning. After hearing this non-word, the participant's task is to try to immediately and precisely repeat it. . For instance, in English, a response of [bilig] or [pilik] would be scored as incorrect; a response [bi:lik], where the vowel is lengthened without change of quality would be scored as correct, because English does not have contrastive vowel length. 43

NWR has been used to seek answers to a variety of theoretical questions, including what
the links between phonology, working memory, and the lexicon are (Bowey, 2001), and how
extensively phonological constraints found in the lexicon affect online production (Gallagher,
2014). NWR is also frequently used in applied contexts, notably as a diagnostic tool for
language delays and disorders (Chiat, 2015; Estes, Evans, & Else-Quest, 2007). Since
non-words can be generated in any language, it has attracted the attention of researchers working
in multilingual and linguistically diverse environments, particularly in Europe (in the context of
diagnosing language impairments among bilingual children (Armon-Lotem, Jong, & Meir, 2015;

```
Chiat, 2015; COST Action, 2009; Meir, Walters, & Armon-Lotem, 2016). NWR scores are
   thought to reflect long-term tasks probably tap into many skills (for relevant discussion see
53
   Coady & Evans, 2008; Santos, Frau, Labrevoit, & Zebib, 2020). Non-words can be designed to
54
   try to isolate certain skills more narrowly; for instance, one can choose non-words that contain
55
   real morphemes in order to load more on prior language experience, or non-words that are
   shorter to avoid loading on working memory (see a discussion in Chiat, 2015). Broadly,
57
   however, NWR scores will necessarily reflect to a certain extent phonological knowledge (to
   perceive the item precisely despite not having heard it before) as well as online phonological
   working memory (to encode the item in the interval between hearing it and saying it back) and
   flexible production patterns (to produce the item precisely despite not having pronounced it
   before). In the present study, we use NWR to investigate the phonological development of
   children learning Yélî Dnye, an isolate language spoken in Papua New Guinea (PNG), which
   has a large and unusually dense phonological inventory. The study was designed to
         The present work. We aimed to contribute to four broad research areas, three via direct
65
   results. areas of research. We motivate each in turn.
66
         NWR and typology.
67
```

The first research area is at the <u>crossing</u>-intersection of typology and phonological 68 development. Previous work using NWR has preferred relatively universal and early-acquired phonemes (with exceptions including Gallagher, 2014), in part as a way to separate phoneme 70 pronunciation from broader syllable structure There has been an interest in adapting NWR to 71 different languages, in part for applied purposes. In a review of NWR as a potential task to 72 diagnose language impairments among bilingual children in Europe, Chiat (2015) discusses the impossibility of creating language-universal non-word items: Languages vary in their phonological inventory, sound sequencing (phonotactics), syllable structure, and word-level prosodic effects (Gallon, Harris, & Van der Lely, 2007) and in part because the test is sometimes used to measure working memory in the context of executive functions (Mulder, Verhagen, Van 77 der Ven, Slot, & Leseman, 2017) rather than purely linguistic skills. Here, we investigate

103

104

- repetition of non-word items containing cross-linguistically common and cross-linguistically
 rare phonetic targets. Specifically, we included a subset of non-word items with typologically
 rare sounds to ask whether these sounds are disadvantaged in the perception-production loop
 involved in NWR. prosody. As a result, any one item created will be relatively easier if it more
 closely resembles real words in a language, making it difficult to balance difficulty when
- comparing children learning different languages. This previous literature also suggests some
- dimensions of difficulty—an issue to which we return in the next subsection.
- Second, we varied the length (in syllables) of Although this cross-linguistic literature is
 rich, the potential difficulty associated with specific phonetic targets composing the non-words
 to contribute to growing has received relatively little attention. For example, Chiat (2015)
 discusses segmental complexity as a function of whether there are consonant clusters which is
 arguably a factor reflecting phonotactics and syllable structure.
- In the present study, we thought it was relevant to represent the rich phonological 91 inventory found in Yélî Dnye, by including a variety of phonetic targets. Some of them are 92 cross-linguistically rare, in that they are less common across languages than other sounds or 93 phonetic targets. Phonologists, phoneticians, and psycholinguists have discussed the extent to which cross-linguistic frequency may reflect ease of processing and acquisition via diachronic language change. These works focus largely on phonotactics (Moreton & Pater, 2012) perceptual parsing of the (ambiguous) linguistic signal (Beddor, 2009; Ohala, 1981), and individual differences in processing styles (Bermúdez-Otero, 2015); small but significant effects that may cumulatively drive language change via phonologization (see Yu, 2021 for a recent review). Thus, the correlation between typological frequency and ease of acquisition is typically 100 assumed to emerge from one or more of the following causal paths: 101
 - 1. Sounds (and sound sequences) that are harder to perceive tend to be misperceived and thus lost diachronically
 - 2. Sounds (and sound sequences) that are harder to pronounce tend to be mispronounced and

thus lost diachronically

105

106

107

109

110

3. Sound sequences that are harder to hold in memory tend to be mispronounced and thus lost diachronically

Given these causal pathways, we predicted that variation in NWR across items will 108 correlate with the cross-linguistic frequency of the phones composing those items.

Length effects on NWR.

The second research area we contribute data to is research looking at the impact of word 111 length on NWR repetition, and what this may reflect about phonological development within 112 specific languages. Some work documents much lower NWR scores for longer, compared to shorter, items ([e.g., among Cantonese-learning children; Stokes, Wong, Fletcher, & Leonard, and Leonard (2006)], whereas differences are negligible in other studies ([e.g., among Italian learners; Piazzalunga, Previtali, Pozzoli, Scarponi, & Schindler, and Schindler (2019).-].

It is possible that differences are due to language-language-specific characteristics, 117 including the modal-most common length of words in the language lexicon and/or in 118 child-directed child-experienced speech in that culture.culture—a hypothesis discussed for 119 instance in Chiat (2015) (pp. 7-8; see also p. 5). In broad terms, one may expect languages with 120 a lexicon that is heavily biased towards monosyllables to show greater length effects than 121 languages where words are modally longer. To see whether there were broad generalizations 122 that could be drawn from previous literature fitting these predictions, we inspected NWR papers 123 in a variety of languages which reported NWR scores separately for different word lengths. We found data for learners of Israeli Arabic (Jaber-Awida, 2018); Cantonese (Stokes et al., 2006); 125 English (Vance, Stackhouse, & Wells, 2005); Italian (Piazzalunga et al., 2019); and Tsimane' (Cristia, Farabolini, Scaff, Havron, & Stieglitz, 2020); and integrated those data with Yélî Dnye 127 results from the present study in Figure ??tend to be longer. A non-systematic meta-analysis 128 does not provide overwhelming support for this hypothesis [Cristia and Casillas (2021); SM1]. 129

NWR scores as a function of age (in years) and item length for comparable studies (2-4 130 indicating number of syllables, 2 = dashed, 3 = dotted, 4 = dotted and dashed). Jaber-Awida 131 (2018) reported on 20 Israeli Arabic learners (orange); Piazzalunga et al. (2019) reported on 132 groups of 24-60 Italian learners (black); Stokes et al. (2006) on 15 Cantonese learners (blue); 133 Vance et al. (2005) on 17-20 English learners (light green); Cristia et al. (2020) reported on 134 groups of 4-6 Tsimane' learners (dark green); the present study reports on groups of 8-19 Yélî 135 Dnye learners (purple). Central tendency is the mean except for Italian and Yélî Dnye (median); 136 error is one standard error. Age has been slightly shifted for ease of inspection of different 137 lengths at a given age. 138

Our reading of this Figure is that, although there is cross-linguistic (or cross-sample) 139 variation in length effects, these do not systematically line up with expected word length in 140 different languages. For instance, the difference in NWR scores for 2-versus 3-syllable items 141 (averaging across age groups) is largest in Tsimane' (~28%) and Arabic (~15%), which tend to 142 have longer words, as does Italian, where the difference between 2- and 3-syllable items was 143 only ~2%. Similarly, two languages that are often described as heavily biased towards 144 monosyllables show diverse length effects (Cantonese ~8% versus English ~1%). Given the 145 Nonetheless, given the paucity of research looking at this question, and the diversity of current results, we do-did not approach this issue within a hypothesis-testing framework but sought instead to provide one more piece of additional data on the question, which may be re-used in future meta- or mega-analytic analyses.

Individual variation correlations with NWR.

150

The third research area we contribute data to relates to the possibility that individual

variation children differ from each other in NWR scores is structured systematic ways.

Although the ideal systematic review is missing, a recent paper comes close with a rather

extensive review of the literature looking at correlations between NWR scores and a variety of

child-level variables, including familial socio-economic status, child vocabulary, and, among

multilingual children, levels of exposure to the language on which the non-words are based

(Farabolini, Rinaldi, Caselli, & Cristia, 2021). In a nutshell, most evidence is mixed, suggesting

that consistent individual variation effects correlations with individual variation may be small,

and more data is needed to estimate their true size. For this reason, we descriptively report

association strength between NWR scores and child age, sex, birth order, and maternal

education. Based on

Our focus on age stems from previous work, we looked at potential increases with where 162 performance increases with child age (Farmani et al., 2018; Kalnak, Peyrard-Janvid, Forssberg, 163 & Sahlén, 2014; Vanceet al., Stackhouse, & Wells, 2005). Prior research typically finds no 164 significant differences as a function of maternal education Although past research has not 165 investigated potential correlations with birth order on NWR, there is a sizable literature on these 166 correlations in other language tasks (e.g., Farmani-Havron et al., 2019), and therefore we report 167 on these too. Common explanations for advantages for first- over later-born children include 168 differential allocation of familial resources, particularly parental behaviors of cognitive 169 stimulation (Lehmann, Nuevo-Chiquero, & Vidal-Fernandez, 2018;-). Regarding child sex, no 170 significant correlation has been found in previous NWR research (Chiat & Roy, 2007), and in 171 other language tasks evidence is mixed. Finally, prior research varies on whether significant 172 differences as a function of maternal education are reported. For instance, no significant 173 difference was found some studies (Balladares, Marshall, & Griffiths, 2016; Kalnak Farmani et 174 al., 2018; Kalnak, Peyrard-Janvid, Forssberg, & Sahlén, 2014; Meir & Armon-Lotem, 2017) or 175 ehild gender (Chiat & Roy, 2007). Although past research has not investigated potential effects 176 of birth order on NWR, there is a sizable literature on these effects in other language tasks (e.g., Havron et al., ; whereas significant differences were reported in others (Santos, Frau, Labrevoit, 178 & Zebib, 2020; Tuller et al., 2018). In other lines of work, maternal education correlates with child language outcomes, including vocabulary reports (Frank, Braginsky, Yurovsky, & 180 Marchman, 2017) and word comprehension studies (Scaff, 2019), and therefore we report on 181 these too. The causal pathways explaining this correlation are complex, but one explanation that 182

is often discussed involves more educated mothers talking more to their children (see discussion in Cristia, Farabolini, Scaff, Havron, & Stieglitz, 2020).

Fourth, these data contribute to the small literature using this task

NWR as a function of language and culture.

The fourth research goal we pursued is to use NWR with non-Western, non-urban populations, speaking a language with a moderate to large phonological inventory (see Maddieson, 2005 for a broad classification of languages based on inventory size). Indeed, NWR has seldom been used outside of urban settings in Europe and North America (Cristia, Farabolini, Scaff, Havron, & Stieglitz, 2020; with exceptions including Gallagher, 2014; Cristia et al., 2020), nor with . To our knowledge, it has never been used with speakers of languages having large phonological inventories (e.g., more than 34 consonants and 7 vowel qualities Maddieson (, 2013b); Maddieson (, 2013a); with no exceptions to our knowledge.

There are no theoretical reasons to presume that the technique will not generalize to these new conditions. That said, Cristiaet al., Farabolini, Scaff, Havron, and Stieglitz (2020) recently reported relatively lower NWR scores among the Tsimane', a non-Western rural population, interpreting these findings as consistent with the hypothesis that lower levels of infant-directed speech and/or low prevalence of literacy in a population could lead to population-level differences in NWR scores.

In view of these results, it is important to bear in mind that NWR is a task developed in countries where literacy is widespread, and it is considered an excellent predictor of reading; for instance, better than rhyme awareness for instance (e.g., Gathercole, Willis, & Baddeley, 1991).

Therefore, it may not be a general index of phonological development, but reflect only instead reflect certain non-universal language skills. Indeed, Cristiaet al., Farabolini, Scaff, Havron, and Stieglitz (2020) present the their task as being a good index of the development of "short-hand-like" representations specifically, which could thus miss, for example, more holistic

216

217

218

219

phonological and phonetic representations. We return to the question of what was measured

here in the Discussion.

Aside from Cristiaet al., Farabolini, Scaff, Havron, and Stieglitz (2020)'s hypotheses just mentioned, we have found little discussion of linguistic effects differences (i.e., potential differences in NWR as a function of language which specific language children are learning, and/or its typology) or cultural effects differences (i.e., potential differences in NWR as a function of other differences across human populations). ¹

Regarding potential language differences, we note that the very fact that studies compose items by varying syllable structure and word length, while preferring relatively simple and universal phones (notably relying on point vowels, simple plosives, and fricatives that are prevalent across languages, like /s/)may indicate a bias towards Indo-European languages, where syllable structure and word length are indeed important structural dimensions. This bias is, of

¹ Please note that the linguistic and cultural differences discussed here are different from the differences discussed in the extensive literature on NWR by bilingual participants. In that literature, authors are concerned with individual variation in exposure to one (as opposed to other) languages among multilingual children, as variation in relative language experiences could mask potential effects of language impairment. To try to measure language abilities above and beyond relative levels of experience with a given language, authors have tried to build non-words that tap language-dependent or language-independent knowledge. For instance, Tuller et al. (2018) employed a set of non-words judged to be language independent and two others that were more aligned with either French or German. The intuition is that NWR will correlate with the relative levels of exposure to that language bilingual children more strongly when items are aligned with a specific language ("language-dependent") than when they are "language-independent." To make this more precise, among bilingual children, those that have more experience with English than Spanish should perform better on English non-words than their peers with less English experience. Preliminary results of an ongoing meta-analysis suggest significant associations between exposure to a given language and performance in both language-dependent and language-independent NWR (Farabolini, Taboh, Ceravolo, & Guerra, 2021). In any case, this line of research focuses on links between exposure to a given language and NWR performance. In contrast, when we discuss linguistic or cultural differences here, we ask the question of whether children vary in their performance as a function of which language they are learning and/or their overall levels of language experience (not relative levels in a multilingual setting).

course, implicit and unintentional, arising as researchers working in other languages attempt to 220 build items that conform to the descriptions of the first investigations using the method, who 221 tend to involve English participants. It would be interesting for future researchers to consider 222 straying from the literature by varying other dimensions that are relevant to the language under 223 study. For instance, for Yélî Dnye, it is relevant to vary phonological complexity of the 224 individual sounds because of its large inventory. 225

Yélî Dnye phonology and community. Before going into the details of our study design, 226 we first give an overview of Yélî Dnye phonology as well as a brief ethnographic review of the developmental environment on Rossel Island. As discussed above, NWR has been almost exclusively used in urban, industrialized populations, so we provide this additional ethnographic information to contextualize the adaptations we have made in running the task and collecting the 230 data, compared to what is typical in commonly studied sites, which are more generally 231 accessible. Laying. Rossel Island lies 250 nautical miles off the coast of mainland PNG and is 232 surrounded by a barrier reef. As a result, transport to and from Rossel Island the island is both 233 infrequent and irregular. International phone calls and digital exchanges that require significant 234 data transfer are typically not an option. Data collection is therefore typically limited to the 235 duration of the researchers' on-island visits. 236

Yélî Dnye phonology.

227

237

Yélî Dnye is an isolate language (presumed Papuan) spoken by approximately 7,000 238 people residing on Rossel Island, an island found at the far end of the Louisiade Archipelago in 239 Milne Bay Province, Papua New Guinea. The Yélî sound system, much like its baroque 240 grammatical system (Levinson, 20202021), is unlike any other in the region. In total, Yélî Dnye uses 90 distinctive segments (not including an additional three rarely used consonants), far outstripping the phoneme inventory size of other documented Papuan languages (Foley, 1986; Levinson, 20202021; Maddieson & Levinson, n.d. in preparation). Thus, with respect to our first research goal, Yélî Dnye is a good language to test-use because its large 245 phonological inventory includes sounds that vary in cross-linguistic frequency (including some

rare sounds) that can be compared in the NWR setting.

To provide some qualitative information on this inventory, we add the following 248 observations. With only four primary places of articulation (bilabial, alveolar, post-alveolar, and 249 velar) and no voicing contrasts, the phonological inventory is remarkably packed with 250 acoustically similar segments. The core oral stop system includes both singleton $(/p/, /t/, /t/^2,$ 251 and /k/) and doubly-articulated (/tp/, /tp/, /kp/) segments, with full-a complete range of nasal 252 equivalents (/m/, /n/, /n/, /n/, /nm/, /nm/, /nm/), and with a substantial portion of them 253 contrastively pre-nasalized or nasally released (/mp/, /nt/, /nk/, /nmtp/, /nmtp/, /nmkp/, /tn/, 254 /kŋ/, /tpnm/, /kpnm/). A large number of this combinatorial set can further be contrastively 255 labialized, palatalized on release, or both (e.g., /p^j/, /p^w/, /p^{jw}/; /tp^j/; /nmdb^j/; see Levinson 256 (20202021) for details). ³ The consonantal inventory also includes a number of non-nasal 257 continuants $(/w/, /j/, /y/, /l/, /\beta^j/, /l\beta^j/)$. Vowels in Yélî Dnye may be oral or nasal, short or 258 long. The 10 oral vowel qualities, which span four levels of vowel height, (/i/, /w/, /u/, /e/, /o/, 259 /9/, /e/, /9/, /e/, /a/) can be produced as short and long vowels, with seven of these able to appear 260 occur as short and long nasal vowels as well $\tilde{1}/\sqrt{\tilde{u}}/\sqrt{\tilde{a}}/\sqrt{\tilde{a}}/\sqrt{\tilde{a}}/\sqrt{\tilde{a}}/\sqrt{\tilde{a}}/\sqrt{\tilde{a}}$. 261

Regarding our Our second research goal , on is to measure the effect of non-word length on NWR, most Yélî Dnye words are disyllabic (~50%), with monosyllabicwords (~40%) appearing most commonly after that, and with tri-and-above syllabic words appearing least frequently (~10%; based on >5800 lexemes in the most recent dictionary at the time of

² We use Levinson's (2021) under-dot notation (e.g., /t/) to denote the post-alveolar place of articulation; these stops are, articulatorily, somewhat variable in place, with at least some tokens produced fully sub-apically. In approximating cross-linguistic segment frequency below we use the corresponding retroflex for each stop segment (e.g., /t/, /tp/, /n/).

³ We use Levinson's (2020) under-dot notation (e.g., /t/) to denote the post-alveolar place of articulation; these stops are, articulatorily, somewhat variable in place, with at least some tokens produced fully sub-apically. In approximating cross-linguistic segment frequency below we use the corresponding retroflex for each stop segment (e.g., /t/, /tp/, /n/).

```
writing; Levinson, 2020) which may need to be interpreted taking into account typical word
266
    length in the language. We estimated word length in words found in a conversational corpus
267
    (see Stimuli section for details), where the distribution of length was: 15% monosyllabic, 39%
268
    disyllabic, 29% trisyllabic, and the remaining 17% being longer than that. The vast majority of
269
    syllables use a CV format. A small portion of the lexicon features words with a final CVC
270
    syllable, but these are limited to codas of -/m/, -/p/, or -/j/ (e.g., ndap /ntæp/ Spondylus
271
    shell'Spondylus shell') and are often resyllabified with an epenthetic /w/ in spontaneous speech
272
    (e.g., ndapî /<del>'ntæ.pu'</del>ntæpu/). There are also a handful of words starting with /æ/ (e.g., ala
273
    /æ-'læ/ here'here') and a small collection of single-vowel grammatical morphemes (see
274
    Levinson (\frac{20202021}{}) for details).
275
```

Our knowledge of Yélî language development is growing (e.g., Brown, 2011, 2014; 276 Brown & Casillas, n.d.in press; Casillas, Brown, & Levinson, 202021; Liszkowski, Brown, 277 Callaghan, Takada, & de Vos, 2012), but research into Yélî phonological development has only 278 just begun. For example, Peute and colleagues' (n.d. Casillas (In preparation) find that Yélî 279 Dnye-learning children's early spontaneous consonant productions appear to exclusively feature 280 simplex and typologically frequent phones. We hope the present study contributes to this 281 growing line of work. Other ongoing work on Yélî Dnye includes experiment-based infant 282 phoneme discrimination data and errors made in elicited and spontaneous speech from young 283 children, but these data are neither finalized nor yet externally reviewed (see Hellwig, Sarvasy, 284 & Casillas, provisionally accepted for more information). These data will help better inform our 285 current analyses based on NWR in the future (e.g., regarding common sound substitutions) but 286 are not critical for testing our current question about the general correlation between 287 cross-linguistic phone frequency and NWR performance. 288

Before closing this section, it bears mentioning that the language has an established 289 orthography, which includes distinct graphemes for all the contrasts on which our items are 290 based. Some children in our sample will have started school. Reading and writing instruction is currently done only in English (other than writing one's name). This was probably not the case
for the majority of mothers of the children in our sample, who will have learned to read and
write in Yélî Dnye during their first three years at school. It is possible that there is also some
home teaching of Yélî reading and writing, notably for reading the bible.

The Yélî community.

Some aspects of the community are relevant for contextualizing our study design and results, particularly regarding sources of individual variation. Specifically, we investigated potential effects of age, gendercorrelations with age, child sex, maternal education, and birth order. There is nothing particular to note regarding age and genderchild sex, but we have some comments that pertain to the other two factors.

The typical household in our dataset includes seven individuals (typically, a mixed sex mixed-sex couple and children—their own and possibly some billeting others others staying with them, as discussed in the next paragraph) and is situated among a collection of four or more other households, with structures often arranged around an open grassy area. These household clusters are organized by patrilocal relation, such that they typically comprise a set of brothers, their wives and children, and their mother and father, with neighboring hamlets also typically related through the patriline. Land attribution for building one's home is decided collectively based on land availability.

Most Yélî parents are swidden horticulturalists, who occasionally fish. Within a group of
households, it is often the case that older adolescents and adults spend their day tending to their
gardens farm plots (which may not be nearby), bringing up water from the river, washing
clothes, preparing food, and engaging in other such activities. Starting around age two years,
children more often spend large swaths of their day playing, swimming, and foraging for fruit,
nuts, and shellfish in large (~10~10 members) independent and mixed-age child play groups
(Brown & Casillas, n.d.; Casillaset al., 2020in press; Casillas, Brown, & Levinson, 2021).
Formal education is a priority for Yélî families, and many young parents have themselves

336

337

339

341

342

343

pursued additional education beyond of what is locally available (Casillaset al., 2020, Brown, & Levinson, 2021). Local schools are well out of walking distance for many children (i.e., more than 1 hour on foot or by canoe each day), so it is very common for households situated close to a school to billet host their school-aged relatives during the weekdays for long segments of the school year. Children start school often at around age seven, although the precise age depends on the child's readiness, as judged by their teacher.

Some general ideas regarding potential maternal education effects on our data correlations 324 between our NWR measures and maternal education may be drawn from the observations above. 325 To begin with, many of our participants above 6 years of age may not be living with their birth mother but with other relatives, which may weaken maternal education effects. Additionally, the importance given to formal education appears relatively stable over the period that Rossel Island 328 has been visited by language researchers (Steven Levinson and Penelope Brown, about 20 329 years). Overall, associations with maternal education. In addition, it seems to us that the length 330 of formal education a given individual may have is not necessarily a good index of their 331 socio-economic status or other individual properties, unlike what happens in industrialized sites, 332 and variation may simply be due to random factors like living close to a school or having 333 relatives there.

As for birth order, much of the work on birth order effects on correlations between birth order and cognitive development (including language) has been carried out in the last 70 years and in agrarian or industrialized settings (Barclay, 2015; Grätz, 2018), where nuclear families are were more likely to be the prevalent rearing environment (Lancy, 2015). It is possible that birth order effects differences are stronger in such a setting, because much of the stimulation can only come from the parents, and when there are multiple children, the inter-birth interval is small enough that older siblings may not be of an age that allows them to contribute to their younger siblings' stimulation. This contrasts with this picture just drawn in the . These effects may be much smaller in cultures where it is common for children to attend daycare at an early

age (such as France) or where extended family typically live close by. The Yélî community, 344 where children will typically benefit from a rich and extensive socially stimulating setting, falls 345 in the latter case, as children are typically surrounded by siblings, and cousins of several orders, 346 regardless of their birth order in their nuclear family. 347

We add some observations that will help us integrate this study to into the broader 348 investigation of NWR across cultures. As mentioned previously, there is one report of lower 349 relatively low NWR scores among the Tsimane', which the authors of that paper interpret as 350 consistent with long-term effects of low levels of infant-directed speech (Cristiaet al., Farabolini, Scaff, Havron, & Stieglitz, 2020). However, Cristiaet al., Farabolini, Scaff, Havron, and Stieglitz (2020) also point out that this is based on between-paper comparisons, and thus 353 methods and a-myriad other factors have not been controlled for. The Yélî community can help 354 us shed further light onto this question gain new insights into this matter because direct speech 355 to children under 3;0 is relatively comparably infrequent in this community too (Casillas (in fact 356 it may be infrequent in many settings, including urban ones Bunce et al., 2020) under review), 357 and additionally shares other societal characteristics wih the Tsimane' [e.g., is rural and relies 358 on farming, children grow up in wide familial networks, etc; Casillas, Brown, and Levinson 359 (2021)]. Although infant-directed speech has been measured in different ways among the 360 Tsimane' and the Yélî communities, our most comparable estimates at present suggests suggest 361 that Tsimane' young children are spoken to about 4.2 minutes per hour (Scaff, Stieglitz, Casillas, 362 & Cristia, 2021), and Yélî children about 3.6 minutes per hour (Casillaset al., 2020, Brown, & 363 Levinson, 2021). Thus, if these input quantities in early childhood are a major determinant of 364 NWR scores relate to lower NWR scores later in life, we should observe similarly low NWR 365 scores here as in Cristiaet al. (, Farabolini, Scaff, Havron, and Stieglitz (2020). 366

In a basic NWR task, the participant listens to a production of a word-like form, such as /bilik/, and then repeats back what they heard without changing any phonological feature that is 368 contrastive in the language. For instance, in English, a response of biligor pilikwould be scored 369

as incorrect; a response bi:lik, where the vowel is lengthened without change of quality would 370 be scored as correct, because English does not have contrastive vowel length. There is some 371 variation in how past NWR studies have designed the presentation procedure and structure of 372 items. For example, while items are often presented orally by the experimenter (Torrington 373 Eaton, Newman, Ratner, & Rowe, 2015), an increasing number of studies have turned instead to 374 playing back pre-recorded stimuli in order to increase control in stimulus presentation 375 (Brandeker & Thordardottir, 2015). Additionally, while some studies have used 10-15 376 non-words (e.g., Cristia et al., 2020), others have employed up to 46 unique items (Piazzalunga 377 et al., 2019). Authors also often modulate structural complexity, typically measured in terms of 378 item length (measured in number of syllables) and/or syllable structure (open as opposed to 379 closed syllables, Gallon et al., 2007). 380

Previous work typically steers clear of articulatorily and/or acoustically challenging 381 sounds, but we included some in our experiment to more adequately represent Yélî Dnye's 382 phonology and to contribute data on whether this affects repetition. We ultimately used a 383 relatively large number of items that would enable us to explore both variation in structural 384 complexity and in more vs. less challenging sounds. However, aware that this large item 385 inventory might render the task longer and more tiresome, we split items across children (see 386 below). Naturally, designing the task in this way may make the study of individual variation 387 within the population more difficult because different children are exposed to different items. 388 However, as discussed above, effects of individual differences in NWR are probably relatively 389 small, and thus we reasoned that they would not be detectable with the sample size that we 390 could collect during our short visit. That said, we contribute to the literature by also reporting 391 descriptive analyses of individual variation that could potentially be integrated in meta- or 392 mega-analytic efforts. 393

Research questions. After some preliminary analyses to set the stage, we perform statistical analyses to inform answers to the following questions:

394

395

- Does the cross-linguistic frequency of sounds in the stimuli predict NWR scores? Are rarer sounds more often substituted by commoner sounds?
 - How do NWR scores change as a function of item length in number of syllables?
- Is individual variation in NWR scores attributable to child age, sex, birth order, and/or maternal education?

Throughout these analyses and in the Discussion, we will also have in mind our fourth goal, namely integrating NWR results across samples varying in language and culture.

We had considered boosting the interpretational value of this evidence by announcing our analysis plans prior to conducting them. However, we realized that even pre-registering an analysis would be equivocal because we would not have enough power to look at all relationships of interest, in many cases possibly not enough to detect any of the known effects associations, given the previously discussed variability across studies. Therefore, all analyses in the present study are descriptive and should be considered exploratory.

409 Methods

398

This study was approved as part of a larger research effort by the second Participants. 410 author. The line of research was evaluated by the Radboud University Faculty of Social 411 Sciences Ethics Committee (Ethiek Commissie van de faculteit der Sociale Wetenschappen; 412 ECSW) in Nijmegen, The Netherlands (original request: ECSW2017-3001-474 413 Manko-Rowland; amendment: ECSW-2018-041), including the use of verbal (not written) 414 consent. As discussed in subsection "The Yélî community," the combination of collective child guardianship practices and common hosting of school-aged children for them to attend school is that adult consent often comes from a combination of aunts, uncles, adult cousins, and grandparents standing in for the child's biological parents. Child assent is also culturally 418 pertinent, as independence is encouraged and respected from toddlerhood (Brown & Casillas, in 419 press). Participation was voluntary; children were invited to participate following indication of 420

436

437

438

439

approval from an adult caregiver. Regardless of whether they completed the task, children were
given a small snack as compensation. Children who showed initial interest but then decided not
to participate were also given the snack.

We tested a total of 55 children from 38 families spread across four hamlet regions. We 424 excluded test sessions from analysis for the following reasons: refused participation or failure to 425 repeat items presented over headphones even after coaching (N=8), spoke too softly to allow 426 offline coding (N=5), or were 13 years old or older (N=2); we tested these teenagers to put 427 younger children at ease). The remaining 40 children (14 girls) were aged from 3 to 10 years (M 428 = 6.40 years, SD = 1.50 years). In terms of birth order, 6 were born first, 5 second, 2 third, 7 429 fourth, 5 fifth, and 1 sixth, with birth order missing for 14 children. These children were tested 430 in a hamlet far from our research base, and we unfortunately did not ask about birth order before 431 leaving the site. Maternal years of education averaged 8.22 years (range 6-12 years).³ We also note that there were 34 children only exposed to Yélî Dnye at home and 6 children exposed to 433 Yélî Dnye plus one or more other languages at home.⁴ 434

Stimuli. Many NWR studies are based on a fixed list of 12-16 items that vary in length between 1 and 4 syllables, often additionally varying syllable complexity and/or cluster presence and complexity, and always meeting the condition that they do not mean anything in the target language (e.g., Balladareset al., Marshall, & Griffiths, 2016; Wilsenach, 2013). We kept the same variation in item length and requirement for not being meaningful in the language, but we

³ We asked for mothers' highest completed level of education. We then recorded the number of years entailed by having completed that level under ideal conditions.

⁴ Most speakers of Yélî Dnye grow up speaking it monolingually until they begin attending school around the age of 7 years; school instruction is in English. While monolingual Yélî Dnye upbringing is common, multilingual families are not unusual, particularly in the region around the Catholic Mission (the same region in which much of the current data were collected), where there is a higher incidence of married-in mothers from other islands (Brown & Casillas, in press). Children in these multilingual families grow up speaking Yélî Dnye plus English, Tok Pisin, and/or other language(s) from the region.

did not vary syllable complexity or clusters because these are vanishingly rare in Yélî Dnye. We also increased the number of items an individual child would be tested on, such that a child 441 would get up to 23 items to repeat (other work has also used up to 24-30 24-46 items: 442 Jaber-Awida, 2018; Kalnaket al., Peyrard-Janvid, Forssberg, & Sahlén, 2014; Piazzalunga, 443 Previtali, Pozzoli, Scarponi, & Schindler, 2019), with the entire test inventory of 40 final items 444 distributed across children. We used a relatively large number of items to explore correlations 445 with length and phonological complexity. However, aware that this large item inventory might 446 render the task longer and more tiresome, we split items across children. Naturally, designing 447 the task in this way may make the study of individual variation within the population more 448 difficult because different children are exposed to different items. 440

A first list of candidate items was generated during a trip to the island in 2018 by selecting 450 simple consonants (/p/, /t/, /k/, /m/, /n/, /w/, /y/) and vowels (/i/, /o/, /u/, /a/, /e/) and 451 combining them into consonant-vowel syllables, then sampling the space of resulting possible 2-452 to 4-syllable sequences. These candidates were automatically removed from consideration if 453 they appeared in Levinson's (2015)dictionary the most recent dictionary (Levinson, 2021). The 454 second author presented them orally to three local research assistants, all native speakers of Yélî 455 Dnye, who repeated each form as they would in an NWR task and additionally let the 456 experimenter know if the item was in fact a word or phrase in Yélî Dnye. Any item reported to 457 have a meaning or a strong association with another word form or meaning was excluded. 458

A second list of candidate items was generated in a second trip to the island in 2019, when
data were collected, by selecting complex consonants and systematically crossing them with all
the vowels in the Yélî Dnye inventory to produce consonant-vowel monosyllabic forms. As
before, items were automatically excluded if they appeared in the dictionary. Additionally, since
perceiving vowel length in isolated monosyllables is challenging, any item that had a short/long
lexical neighbor was excluded. Because there is still much to discover about the phonology and
phonetics of Yélî Dnye (Levinson, 2020), it was also possible that we initially generated items

with illegal, but currently undocumented constraints. Therefore, we Additionally, we made sure 466 that the precise consonant-vowel sequence occurred in some real word in the dictionary (i.e., 467 that there was a longer word included the monosyllable as a sub-sequence). These candidates 468 were then presented to one informant, for a final check that they did not mean anything. 469 Together with the 2018 selection, they were recorded, based on their orthographic forms, using a 470 Shure SM10A XLR dynamic headband microphone and an Olympus WS-832 stereo audio 471 recorder (using an XLR to mini-jack adapter) by the same informant, monitored by the second 472 author for clear production of the phonological target. The complete recorded list was finally 473 presented to two more informants, who were able to repeat all the items and who confirmed 474 there were no real words present. Despite these checks, one monosyllable was ultimately 475 frequently identified as a real word in the resulting data (intended yî /yw/; identified as yi /yi/, 476 tree tree'. Additionally, an error was made when preparing files for annotation, resulting in two items being merged (tpå /tpa/ and tp:a /tpæ/). These three problematic items are not described 478 here, and removed from the analyses below.

The final list includes three practice items and 40 test items (across infants): 16
monosyllables containing sounds that are less frequent in the world's languages than singleton
plosives; 8 bisyllables; 12 trisyllables; and 4 quadrisyllables (see Table 1).

A Praat script (Boersma & Weenink, 2020) was written to randomize this list 20 times, and to split it into two sub-lists, to generate 40 different elicitation sets. The 40 elicitation sets are available online from osf.io/dtxue/. The split had the following constraints:

• The same three items were selected as practice items and used in all 40 elicitation sets.

- Splits were done within each length group from the 2018 items (i.e., separately for 2-, 3-, and 4-syllable items); and among onset groups for the difficult monosyllables generated in 2019 (i.e., all the monosyllables starting with /tp/ were split into 2 sub-lists). Since some of these groups had an odd number of items, one of the sub-lists was slightly longer than the other (20 vs. 23).
 - Once the sub-list split had been done, items were randomized such that all children heard first the 3 practice items in a fixed order (1, 2, and 4 syllables), a randomized version of their sub-list selection of difficult onset items, and randomized versions of their 2-syllable, then 3-syllable, and finally 4-syllable items.
 - Cross-linguistic frequency.

To inform our analyses, we estimated the typological frequency of all phonological segments present in the target items using the PHOIBLE cross-linguistic phonological inventory database (Moran & McCloy, 2019). For each phone in our task, we extracted the number and percentage of languages noted to have that phone in its inventory. While PHOIBLE is an unprecedentedly comprehensive databasea unprecedented in its scope, with phonological inventory data for over 2000 languages at the time of writing, it is of course still far from complete, which may mean that frequencies are estimates rather than precise descriptors. Note that nearly half of the segment types phones in PHOIBLE are only attested in one language (Steven Moran, personal communication). Extrapolating from this observation, we treat the three segments in our stimuli that were unattested in PHOIBLE (/lβ^j/, /tp/, and /tp/) as having a frequency of 1 (i.e., appearing in one language), with a (rounded) percentile of 0% (i.e., its cross-linguistic percentile is zero).

Within-language frequency.

Additionally, we estimated the usage frequency of the phones present in the target items in a corpus of child-centered recordings (Casillaset al. , Brown, & Levinson, 2021). That corpus was constituted by sampling from audio-recordings (7–9 hours long), collected as 10 children

525

527

529

531

532

533

534

535

aged between 1 month and 3 years went about their day. The researchers selected 9 2.5-minute 513 clips randomly and 11 1- or 5-minute clips by hand (selected to represent peak turn-taking and 514 child vocal activity). These clips were segmented and transcribed by the lead researcher and a 515 highly knowledgeable local assistant, who speaks Yélî Dnye natively, has ample experience in 516 this kind of research, and often knew all the recorded people personally. For more details, 517 please refer to Casillas, Brown, and Levinson (2021). 518

For the present study, we extracted the transcriptions of adult speech (i.e., removing key 519 child and other children's speech) and split them into words using white space. We then 520 removed all English and Tok Pisin words. The resulting corpus contained a total of 18, 2020) by counting the 934 word tokens of 1,686 unique word types. To get our phone frequency measure, 522 we counted the number of word types in which they the phone occurred, and applied the natural 523 logarithm.⁵ Here, unattested sounds were not considered (i.e., they were declared NA so that 524 they do not count for analyses). Note that the resulting values estimate usage frequencies for very young children's input and, while this is somewhat different from what our older participants experience on a daily basis, we can expect that this is a reasonable approximation of the early input that formed the foundation of their phonological knowledge. 528

There is some variation in procedure in previous work. For example, while items are often presented orally by the experimenter (Torrington Eaton, Newman, Ratner, & Rowe, 2015), an increasing number of studies have turned instead to playing back pre-recorded stimuli in order to increase control in stimulus presentation (Brandeker & Thordardottir, 2015).

In adapting the typical NWR procedure for this our context, we balanced three desiderata: That children would not be unduly exposed to the items before they themselves had to repeat them (i.e., from other children who had participated); that children would feel comfortable doing

⁵ We also carried out analyses using token (rather than type) phone frequency, but this measure was not correlated with whole-item NWR scores, and therefore the fact that it did not explain away the predictive value of cross-linguistic phone frequency was less informative than the relationship discussed in the Results section.

542

543

545

560

this task with us; and that community members would feel comfortable having their children do
this task with us.

We tested in four different sites spread across the northeastern region of the island, making a single visit to each, conducting back-to-back testing of all eligible children present at the time of our visit in order to prevent the items from 'spreading' between children through hearsay. Whenever children living in the same household were tested, we tried to test children in age order, from oldest to youngest, to minimize intimidation for younger household members, and always using different elicitation sets. Because space availability was limited in different ways from hamlet to hamlet, the places where elicitation happened varied across testing sites. More information is available from the online supplementary materials.

We fitted the child with a headset microphone (Shure SM10A or WH20 XLR with a 546 dynamic microphone on a headband, most children using the former) that fed into the left 547 channel of a Tascam DR40x digital audio recorder. The headsets were designed for adult use 548 and could not be comfortably seated on many children's heads without a more involved adjustment period. To minimize adjustment time, which was uncomfortable for some children 550 given the proximity of the foreign experimenter and equipment, we placed the headband on children's shoulders in these cases, carefully adjusting the microphone's placement so that it was still close to the child's mouth. A research assistant who spoke Yélî Dnye natively, and who could also hear the instructions over headphones, sat next to the child throughout the task to provide instructions and, if needed, encouragement. The research assistant coached the child throughout the task to make sure that they understood what they were expected to do. An Finally, an experimenter (the first author) delivered was also fitted with headphones and a 557 microphone; she was in charge of delivering the pre-recorded stimuli to the research 558 assistantand the child, the child, and herself over headphones. 559

The first phase of the experiment involved making sure the child understood the task. We explained the task and then orally presented the first practice item. At this point, many children

did not say anything in response, which triggered the following procedure: First, the assistant 562 insisted the child make a response. If the child still did not say anything, the assistant said a real 563 word and then asked the child to repeat it, then another and another. If the child could repeat 564 real words correctly, we provided the first training item over headphones again for children to 565 repeat. Most children successfully started repeating the items at this point, but a few needed 566 further help. In this case, the assistant modeled the behavior (i.e., the child and assistant would 567 hear the item again, and the assistant would repeat it; then we would play the item again and ask 568 the child to repeat it). A small minority of children still failed to repeat the item at this point. If 569 so, we tried again with the second training item, at which point some children demonstrated task 570 understanding and could continue. A fraction of the remaining children, however, failed to 571 repeat this second training item, as well as the third one, in which case we stopped testing altogether (see Participants section for exclusions).

The second phase of the experiment involved going over the list of test items randomly 574 assigned to each child. This was done in the same manner as the practice items: the stimulus 575 was played over the headphones, and then the child repeated it aloud. NWR studies vary in 576 whether children are allowed to hear and/or repeat the item more than one time. We had a fixed 577 procedure for the test items (i.e., the non-practice items) in which the child was allowed to make 578 further attempts if their first attempt was judged erroneous in some way by the assistant. The 579 procedure worked as follows: When the child made an attempt, the assistant indicated to the 580 experimenter whether the child's production was correct or not. If correct, the experimenter 581 would whisper this note of correct repetition into a separate headset that fed into the right channel of the same Tascam recorder and we moved on to the next item. If not, the child was allowed to try again, with up to five attempts allowed before moving on to the next item. Children were not asked to make repetitions if they did not produce a first attempt. In total, test 585 sessions took approximately six minutes, with the first minute attributed to practice and five 586 minutes to the actual test list. 587

The first author then annotated the onset and offset of all children's productions 588 from the audio recording using Praat audio annotation software (Boersma & Weenink, 2020), 580 then ran a script to extract these tokens, pairing them with their original auditory target stimulus, 590 and writing these audio pairs out to .way clips. The assistant then listened through all these 591 paired target-repetition clips randomized across children and repetitions, grouped such that all 592 the clips of the same target were listened to in succession. For each clip, the assistant indicated 593 in a notebook whether the child production was a correct or incorrect repetition and 594 orthographically transcribed the production, noting when the child uttered a recognizable word 595 or phrase and adding the translation equivalent of that word/phrase into English. The assistant 596 was also provided with some general examples of the types of errors children made without 597 making specific reference to Yélî sounds or the items in the elicitation sets. Because the 598 phonological inventory is so acoustically packed and annotation was done based on audio data alone, it might be easy to misidentify a segment. Therefore, the assistant double-checked all of her annotations by listening to them and assessing them a second time, once she had completed a full first round.

Previous work typically reports two scores: a binary word-level exact 603 repetition score, and a phoneme-level score, defined as the number of phonemes that can be 604 aligned across the target and attempt, divided by the number of phonemes of whichever item 605 was longer (the target or the attempt; as in Cristiaet al., Farabolini, Scaff, Havron, & Stieglitz, 606 2020). Previous work does not use distance metrics, but we report these rather than the 607 phoneme-level scores because they are more informative. To illustrate these scores, recall our 608 example of an English target being /bilik/ with an imagined response [bilig]. We would score this response as follows: at the whole item level this production would receive a score of zero (because the repetition is not exact); at the phoneme level this production would receive a score of 80% (4 out of 5 phonemes repeated exactly); and the phone-based Levenshtein distance for 612 this production is 20% (because 20% of phonemes were substituted or deleted). Notice that the 613 phone-based Levenshtein distance is the complement of the phoneme-level NWR score. An

advantage of using phone-based Levenshtein distance is that it is scored automatically with a script, and it can then easily be split in terms of deletions and substitutions (insertions were not attested in this study).

This study was approved as part of a larger research effort by the second author. The line 618 of research was evaluated by the Radboud University Faculty of Social Sciences Ethics 619 Committee (Ethiek Commissie van de faculteit der Sociale Wetenschappen; ECSW) in 620 Nijmegen, The Netherlands (original request: ECSW2017-3001-474 Manko-Rowland; 621 amendment: ECSW-2018-041). As discussed in subsection, the combination of collective child guardianship practices and common billeting of school-aged children for them to attend school 623 is that adult consent often comes from a combination of aunts, uncles, adult cousins, and 624 grandparents standing in for the child's biological parents. Child assent is also culturally 625 pertinent, as independence is encouraged and respected from toddlerhood (Brown & Casillas, 626 n.d.). Participation was voluntary; children were invited to participate following indication of 627 approval from an adult caregiver. Regardless of whether they completed the task, children were 628 given a small snack as compensation. Children who showed initial interest but then decided not 629 to participate were also given the snack.

We tested a total of 55 children from 38 families spread across four hamlet regions. We
excluded test sessions from analysis for the following reasons: refused participation or failure to
repeat items presented over headphones even after coaching (N=8), spoke too softly to allow
offline coding (N=5), or were 13 years old or older (N=2; we tested these teenagers to put
younger children at ease). The remaining 40 children (14 girls) were aged from 3 to 10 years (M
= 6.50 years, SD = 1.50 years). In terms of birth order, 6 were first borns, 5 second, 2 third, 7
fourth, 5 fifth, and 1 sixth, with birth order missing for 14 children. These children were tested
in a hamlet far from our research base, and we unfortunately did not ask about birth order before

leaving the site. Maternal years of education averaged 8.22 years (range 6-12 years). We also
note that there were 34 children only exposed to Yélî Dnye at home and 6 children exposed to
Yélî Dnye plus one or more other languages at home.

642 Results

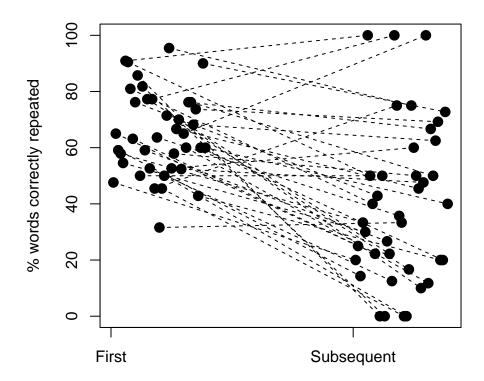

Figure 1. Whole-item NWR scores for individual participants averaging separately their first attempts and all other attempts.

Preliminary analyses. We first checked whether whole-item NWR scores varied between first and subsequent presentations of an item by averaging word-level scores at the participant

⁶ We asked for mothers' highest completed level of education. We then record the number of years entailed by having completed that level under ideal conditions.

Most speakers of Yélî Dnye grow up speaking it monolingually until they begin attending school around the age of 7 years; school instruction is in English. While monolingual Yélî Dnye upbringing is common, multilingual families are not unusual, particularly in the region around the Catholic Mission (the same region in which much of the current data were collected), where there is a higher incidence of married-in mothers from other islands (Brown & Casillas, n.d.). Children in these multilingual families grow up speaking Yélî Dnye plus English, Tok Pisin, and/or other language(s) from the region.

level separately for first attempts and subsequent repetitions. We excluded 1 child who did not have data for one of these two types. As shown in Figure 1, participants' mean word-level 646 scores became more heterogeneous in subsequent repetitions. Surprisingly, whole-item NWR 647 scores for subsequent repetitions (M = 40, SD = 28) were on average lower than first ones (M 648 = 65, SD = 15), t(38) = 5.89, p < 0.001; Cohen's d = 1.13). Given uncertainty in whether 649 previous work used first or all repetitions, and given that score here declined and became more 650 heterogeneous in subsequent repetitions, we focus the remainder of our analyses only on first 651 repetitions, with the exception of qualitative analyses of substitutions.

Taking into account only the first attempts, we derived overall averages across all items. 653 The overall NWR score was M = 65% (SD = 15%), Cohen's d = 4.39. The phoneme-based 654 normalized Levenshtein distance was M = 21% (SD = 9%), meaning that about a fifth of 655 phonemes were substituted or deleted. 656

We also looked into the frequency with which mispronunciations resulted in real words. In 657 fact, two thirds of incorrect repetitions were recognizable as real words or phrases in Yélî Dnye 658 or English: 63%. This type of analysis is seldom reported. We could only find one comparison 659 point: Castro-Caldas, Petersson, Reis, Stone-Elander, and Ingvar (1998) found that illiterate 660 European Portuguese adults' NWR mispronunciations resulted in real words in 11.16% of cases, 661 whereas literate participants did so in only 1.71% of cases. The percentage we observe here is 662 much higher than reported in the study by Castro and colleagues' study, but we do not know 663 whether age, language, test structure, or some other factor explains this difference, such as the 664 particularities of the Yélî Dnye phonological inventory, which lead any error to result in many 665 true-word phonetic neighbors. Follow-up work exploring this type of error in children from other populations in addition to further work on Yélî children may clarify this effect association. NWR and typology: NWR as a function of cross-linguistic phone frequency. Turning to 668 our first research question, we analyzed variation in whole-item NWR scores as a function of the 669 average frequency with which sounds composing individual target words are found in languages

685

686

687

688

689

over the world. To look at this, we fit a mixed logistic regression in which the outcome variable
was whether the non-word was correctly repeated or not. The fixed effect of interest was the
average cross-linguistic phone frequency; we also included child age as a control fixed effect,
and allowed slopes in interaction with cross-linguistic phone frequency, and allowed intercepts
to vary over the random effects child ID and target ID.

We could include 826 observations, from 40 children producing in any given trial one of 676 40 potential target words. The analysis revealed a main effect of age ($\beta = 0.350.39$, SE $\beta =$ 677 0.13, p < 0.01); and, with older children repeating more items correctly. It also revealed a 678 significant estimate for the scaled average cross-linguistic frequency of phones in the target 679 words ($\beta = 0.780.80$, SE $\beta = 0.19$, p < 0.001): Target words with phones found more 680 frequently across languages had higher correct repetition scores, as shown in Figure 2. 681 Averaging across participants, the Pearson correlation between scaled average cross-linguistic 682 phone frequency and whole-item NWR scores was r(38) = .544. 683

Additionally, the effect for the interaction between the two fixed effects was small but significant ($\beta = 0.22$, SE $\beta = 0.09$, p = 0.01): The effect of frequency was larger for older children. Inspection of Figure 3 suggests that the age effects are more marked for items containing cross-linguistically common phones, such that children's average performance increases more rapidly with age for those than for items containing cross-linguistically uncommon phones.

NWR and typology: NWR as a function of within-language phone frequency. We next checked whether the association between whole-item NWR scores and cross-linguistic phone frequency could actually be due to frequency of the sounds within the language: One can suppose that sounds that occur more frequently across languages are also. The same perception and production pressures that shape languages diachronically could affect a language's lexicon, so that sounds that are easier to perceive or produce are more frequent within a language, and therefore may be easier for children to than those that are harder. If so, children will have more

698

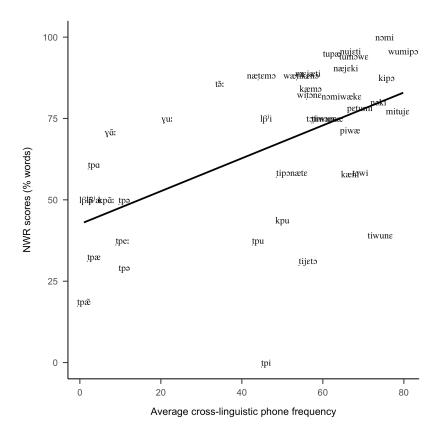

Figure 2. NWR scores for individual target words as a function of the average frequency with which each phone is found across languages.

experience with the easier sounds, and they may thus be better able to to represent and repeat non-words containing them simply because of the additional exposure.

Phone corpus-based frequencies were correlated with phone cross-linguistic frequencies 690 [r(27) = 0.50, p < 0.01]; and item-level average phone corpus-based frequencies were correlated 700 with the corresponding cross-linguistic frequencies [r(38) = 0.73, p < 0.001]. Moreover, 701 averaging across participants, the Pearson correlation between scaled average corpus phone frequency and whole-item NWR scores was r(38) = .432, p < 0.01. Therefore, we fit another 703 mixed logistic regression, this time declaring as fixed effects both scaled cross-linguistic and 704 corpus frequencies (averaged across all attested phones within each stimulus item), in addition 705 to age. As before, the model contained random slopes for both child ID and target. In this 706 model, both cross-linguistic phone frequency ($\beta = 0.78$, SE $\beta = 0.27$, p < 0.01) and age ($\beta = 0.78$, SE $\beta = 0.27$, p < 0.01) 707

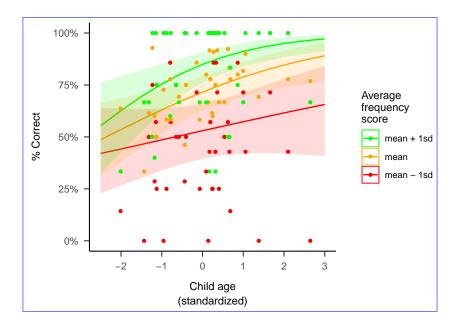

Figure 3. NWR scores as a function of age and typological frequency. Lines are fits from the model in the main text predicting NWR scores from child age (x axis) and the average frequency with which each phone is found across languages (mean, or plus/minus one standard deviation). Each circle indicates the estimated NWR scores for one child at one frequency level.

 $_{708}$ 0.35, SE β = 0.13, p < 0.01) were significant predictors of whole-item NWR scores, but corpus phone frequency (β = 0.00, SE β = 0.25, p = 0.99) was not.

Follow-up analyses: Patterns in NWR mispronunciations. We addressed our first 710 research question in a second way, by investigating patterns of error, looking at all attempts and 711 not excluding errors resulting in real words, so as to base our generalizations on more data. 712 There were no cases of insertion, Insertions and deletions were very rare (metathesis was not 713 attested): there were only $\frac{12-17}{1}$ instances of deleted vowels ($\frac{-0.28}{0.35}$ % of all vowel targets), 714 and 6-13 instances of deleted consonants ($\sim 0.19 \sim 0.50\%$ of all consonant targets). We therefore focus our qualitative description here on substitutions: There were 820-813 cases of 716 substitutions, ~ 16.95 of the 4839 of the phones found collapsing across all children and target 717 words, so that substitutions constituted the frank majority of incorrect phones (~ 97.74 of 718 unmatched phones). To inform our understanding of how cross-linguistic patterns may be 719 reflected in NWR scores, we asked: Is it the case that cross-linguistically less common and/or 720

732

733

734

more complex phones are more frequently mispronounced, and more frequently substituted by
more common ones than vice versa?⁶

Table 2

Number (and percent) of vowel targets that were correctly repeated (Corr.), deleted (Del.), or substituted, as a function of vowel type, and whether the error resulted in a nasality change (Nasal Err.) or only a quality change (Qual. Err.)

	Corr.	Del.	Nasal Err.	Qual. Err	% Corr.	% Del.	% Nasal Err.	% Qual E
Nasal Target	100-101	0	39	17	64.1-64.3	0.0	25.0-24.8	10.9 10
Oral Target	1992 - <u>1988</u>	12 <u>17</u>	52	205 - <u>204</u>	88.1-87.9	0.5-0.8	2.3	9.1

We looked for potential asymmetries in errors for different types of sounds in vowels by 723 looking at the proportion of vowel phones that were correctly repeated or not, generating 724 separate estimates for nasal and oral vowels. The nasal vowels in our stimuli occur in 725 ~1.40~1.40% of languages' phonologies (range 0% to 3%); whereas oral vowels in our stimuli 726 occur in ~31.55~31.55% of languages' phonologies (range 3% to 92%). As noted above, type 727 frequency within the language is correlated with cross-linguistic frequency, and thus these two 728 types of sounds also differ in the former: Their type-frequencies in Yélî Dnye are: nasal vowels 729 $\sim 0.03 \sim 0.03\%$ (range 0.00% to 0.05%) versus oral $\sim 0.23 \sim 0.23\%$ (range 0.02% to 0.76%). 730

We distinguished errors that included a change of nasality (and may or may not have preserved quality), versus those that preserved nasality (and were therefore a quality error), shown in Table 2. We found that errors involving nasal vowel targets were more common than those involving oral vowels (35.90 versus 11.9035.70 versus 12.10). Additionally, errors in which a nasal vowel lost its nasal character were 10 times more common than those in which an oral vowel was produced as a nasal one. Note that this analysis does not tell us whether

⁶ Note that tables of errors including child age are provided in the project repository for those interested in a finer-grained analysis than what is presented here. See https://osf.io/5qspb/wiki/home/, quick links, error tables.

749

750

751

752

cross-linguistic or within-language frequency is the best predictor, an issue to which we return below.

Table 3

Number (and percent) of consonant targets that were correctly repeated (Corr.), deleted (Del.), or substituted, as a function of the complexity of the consonant, and whether the error resulted in a change of complexity (Cmpl Err.) or not (Othr Err.)

	Corr.	Del.	Cmpl Err.	Othr Err.	% Corr.	% Del	% Cmpl Err.	% Othr
Complex Target	257 - <u>198</u>	0	218 - <u>219</u>	48-44	49.1 - <u>43.0</u>	0.0	41.7-47.5	9.2
Simple Target	1425-1482	6-13	2–3	120 - <u>117</u>	91.8	0.4-0.8	0.1-0.2	7.7

For consonants, we inspected complex ([tp], [tp], [kp], [km], [kn], [mp], [y], and [lβ^j])
versus simpler ones ([m], [n], [l], [w], [j], [w], [t], [g], [p], [t], [k], [f], [h], and [tʃ]), using the
same logic: We looked at correct phone repetition, substitution with a change in complexity
category, or a change within the same complexity category.⁷ The complex consonants in our
stimuli occur in ~17.33~17.33% of languages' phonologies (range 0% to 78%); whereas simple
consonants in our stimuli occur in ~67.62~67.62% of languages' phonologies (range 13% to
96%). Again these groups of sounds differ in their frequency within the language. Their type
frequencies in Yélî Dnye are: complex consonants ~0.04~0.04% (range 0.00% to 0.10%)
versus simple consonants ~0.32~0.32% (range 0.06% to 0.55%).

Table 3 showed that errors involving complex consonant targets were more common than those involving simple consonants (50.90-57 versus 8.20%). Additionally, errors in which a complex consonant was mispronounced as a simple consonant were quite common, whereas those in which a simple consonant was produced as a complex one were vanishingly rare.

⁷ Note that the substitutions included phones that are not native to Yélî Dnye but do occur in English (e.g., [t∫]). These data come from careful transcriptions by a native Yélî Dnye speaker who is very fluent in English.

754

755

756

757

758

759

760

To address whether errors were better predicted by cross-linguistic or within-language frequency, we calculated a proportion of productions that were correct for each phone (regardless of the type of error or the substitution pattern). Graphical investigation suggested that in both cases the relationship was monotonic and not linear, so we computed Spearman's rank correlations between the correct repetition score, on the one hand, and the two possible predictors on the other. Although we cannot directly test the interaction due to collinearity, the correlation with cross-linguistic frequency [r(319.72346.78) = 0.760.74, p < 0.001] was greater than that with within-language frequency [r(731.10817.23) = 0.450.39, p = 0.050.09].

Length effects on NWR. We next turned to our second research question by inspecting 761 whether NWR scores varied as a function of word length (Table 4). In this section and all subsequent ones, we only look at first attempts, for the reasons discussed previously. 763 Additionally, we noticed that participants scored much lower on monosyllables than on 764 non-words of other lengths. This is likely due to the fact that the majority of monosyllables 765 were designed to include sounds that are rare in the world's languages, which may be harder to 766 produce or perceive, as suggested by our previous analyses of NWR scores as a function of 767 cross-linguistic phone frequency and error patterns. Therefore, we set monosyllables aside for 768 this analysis. 769

We observed the typical pattern of lower scores for longer items only for the whole-item 770 scoring, and even there differences were rather small. In a generalized binomial mixed model 771 excluding monosyllables, we included 479 observations, from 40 children producing, in any 772 given trial, one of 24 (non-monosyllabic) potential target words. The analysis revealed a 773 positive effect of age ($\beta = 0.56$, SE $\beta = 0.14$, p < 0.001) and a negative but non-significant 774 estimate for target length in number of syllables ($\beta = -0.15$, SE $\beta = 0.33$, p = 0.65). 775 Individual variation and NWR. Our final exploratory analysis assessed whether variation in scores was structured by factors that vary across individuals, as per our third research 777 question. As shown in Figure 4, there was a greater deal of variance across the tested age range, 778 with significantly higher NWR scores for older children (Spearman's rank correlation, given

Table 4

NWR means (and standard deviations) measured in whole-word scores and normalized Levenshtein Distance (NLD), separately for the four stimuli lengths.

	Word	NLD
1 syll	48 (22)	40 (18)
2 syll	79 (22)	8 (9)
3 syll	78 (19)	7 (7)
4 syll	74 (32)	9 (12)

inequality of variance, $\rho(5,649.08)=.47$, p<0.01). In contrast, there was no clear association between NWR scores and sex (Welch t (27.33) = -0.60, p=0.56), birth order (data missing for 14 children, $\rho(3,502.90)=-.198$, p=0.33), or maternal education ($\rho(9,628.60)=.097$, p=0.55).

784 Discussion

We used non-word repetition to investigate phonological development in a language with 785 a large phonological inventory (including some typologically rare segments). We aimed to 786 provide additional data on two questions already visited in NWR work, namely the influence of 787 stimulus length and individual variation, plus one research area that has received less attention, 788 regarding the possible relationship between correlation between typological phone frequency 789 and NWR scores. An additional overarching goal was to discuss NWR in the context of population and language diversity, since it is very commonly used to document phonological development in children raised in urban settings with wide-spread literacy, and has been less seldom used in non-European languages (but note there are exceptions, including work cited in 793 the Introduction and in the Discussion below). We consider implications of our results on each 794 of these four research areas in turn.

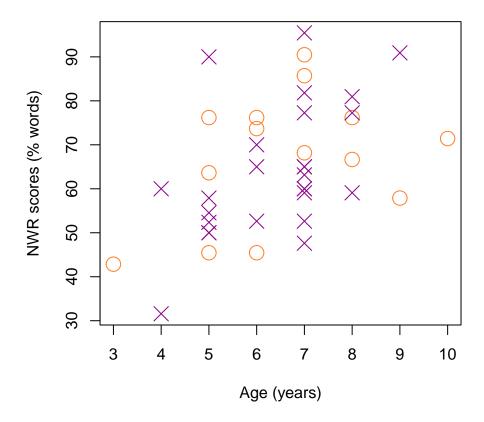

Figure 4. NWR whole-item scores for individual participants as a function of age and sex (purple crosses = boys, orange circles = girls).

NWR and typology. Arguably the most innovative aspect of our data relate to the 796 inclusion of phones that are less commonly found across languages, and rarely used in NWR 797 tasks. Our monosyllabic items included typologically rare segments so that we could test 798 whether lower average segmental frequency is associated with lower NWR scores. It would 799 stand to reason that typologically common sounds are associated with higher performance, but 800 to our knowledge this has not yet been tested with NWR. As explained in the Introduction, 801 typological frequency of phones could reflect ease of perception, ease of production, and other 802 factors, and these factors could affect speech processing and production. This predicts a 803 correlation between typological frequency and NWR performance, due to those factors affecting both. To assess this prediction, we looked at our data in two ways. First, we measured the 805 degree of association between NWR scores and cross-linguistic frequency at the level of 806 non-word items. Second, we described mispronunciation patterns, by looking at correct and 807

incorrect repetitions of simpler and more complex sounds, which are also more or less frequent.

There are some reasons to believe that Yélî Dnye put that hypothesis to a critical test: The 800 phonemic phoneme inventory is both large and acoustically packed, in addition to containing 810 several typologically infrequent (or unique) contrasts. One could then predict that this effect 811 correlations with typological frequency should be relatively weak because the ambient language 812 puts more pressure on Yélî children to distinguish (perceptually and articulatorily) fine-grained 813 phonetic differences in order to successfully communicate with others, than what is required of 814 child speakers of other languages. On the other hand, it is also possible that this pressure gives Yélî children no benefit, and that some of these categories are simply acquired later in development. We can draw a parallel with children learning another Papuan language, Ku Waru, which has a packed inventory of lateral consonants; children do not produce adult-like 818 realizations of the more complex of these laterals (the pre-stopped velar lateral $\widehat{\text{QL}}$) until 5 or 6 819 years of age (Rumsey, 2017) 820

And yet, we found a robust effect We do not have the necessary data to assess whether the 821 correlation is indeed weaker for Yélî Dnye learners than learners of other languages, but we did 822 find a robust correlation of average segmental cross-linguistic frequency on and NWR 823 performance: Even accounting for age and random effects of item and participant, we saw that 824 target words with typologically more common segments were repeated correctly more often. 825 This effect was large, with a magnitude more than twice the size of the effect of participant age. 826 Moreover, this significant effect remained even once also Additionally, we observed an interaction between age and this factor, which emerged because cross-linguistic frequency explained more variance at older ages (i.e., the difference in performance for more versus less typologically frequent sounds was greater for older than younger children). Importantly, the correlation between performance and typological frequency remained significant after 831 accounting for the frequencies of these segments in Yélî Dnye children's input a conversational 832 corpus. An analysis of the substitutions made by children also aligned with this interpretation, 833

with typologically more common sounds being substituted for typologically less common ones.

We thus at present conclude that typological frequency of sounds is, to a certain extent, 835 mirrored in children's NWR, in ways that may not be due merely to how often those sounds are 836 used in the ambient language, and which are not erased by language-specific pressure to make 837 finer-grained differences early in development. We do not aim to reopen a debate on the extent 838 to which cross-linguistic frequency of occurrence can be viewed necessarily as reflecting ease of 839 perception or production (most often discussed in the case of phonotactic constraintson 840 sequences, via phonotactic constraints, ambiguous parsing conditions, individual differences, and more as in, e.g., Beddor, 2009; Bermúdez-Otero, 2015; Maddieson, 2009; Ohala, 1981; Yu, 2021), but we do point out that this effect association is interestingly different from effects found 843 in artificial language learning tasks (see Moreton & Pater, 2012 for a review) which are in some ways quite similar to NWR. We believe that it may be insightful to extend the purview of NWR from a narrow focus on working memory and structural factors to broader uses, including for describing the fine-grained phonetic phonological representations in the perception-production loop (as in e.g., Edwards, Beckman, & Munson, 2004). 848 Length effects and NWR. We investigated the effect of item complexity on NWR scores 840 by varying both the number of syllables in the item. In broad terms, children should have higher 850 NWR scores for shorter items. That said, previous work summarized in the Introduction has 851 shown both very small (e.g., Piazzalungaet al., Previtali, Pozzoli, Scarponi, & Schindler, 2019) 852 and very large (e.g., Cristiaet al., Farabolini, Scaff, Havron, & Stieglitz, 2020) effects of 853 stimulus length. Setting aside our monosyllabic stimuli (which contained typologically 854 infrequent segments with lower NWR scores, as just discussed), we examined effects of item length among the remaining stimuli, which range between 2 and 4 syllables long. The effect of item length was not significant in a statistical model that additionally accounted for age and random effects of item and participant, and is small and inconsistent across ages (see Figure ??). 858 We do not have a good explanation for why samples in the literature vary so much in terms of 850 the size of length effects, but two possibilities are that this is not truly a length effect but a 860

confound with some other aspect of the stimuli, or that there is variation in phonological representations that is poorly understood. We explain each idea in turn.

First, it remains possible that apparent length effects are actually due to uncontrolled
aspects of the stimuli. For instance, some NWR researchers model their non-words on existing
words, by changing some vowels and consonants, which could lead to fewer errors (since
children have produced similar words in the past); some researchers control tightly the diphone
frequency of sub-sequences in the non-words. Building on these two aspects that researchers
often control, one can imagine that longer items have fewer neighbors, and thus both the
frequency with which children have produced similar items and (elatedly relatedly) their n-phone
frequency is overall lower. If this idea is correct, a careful analysis of non-words used in
previous work may reveal that studies with larger length effects just happened to have longer
non-words with lower n-phone frequencies.

Second, NWR is often described as a task that tests flexible perception-production, and as 873 such it is unclear why length effects should be observed at all. However, it is possible that NWR 874 relies on more specific aspects of perception-production, in ways that are dependent on stimulus 875 length. A hint in this direction comes from work on illiterate adults, who can be extremely 876 accurate when repeating short non-words, but whose NWR scores are markedly lower for longer 877 items. In a longitudinal study on Portuguese-speaking adults who were learning to read, 878 Kolinsky, Leite, Carvalho, Franco, and Morais (2018) found that, before reading training, the 879 group scored 12.5% on 5-syllable items, whereas after 3 months of training, they scored 62.5% 880 on such long items, whereas performance was at 100% for monosyllables throughout. Given that as adults they had fully acquired their native language, and obviously they had flexible perception-production schemes that allowed them to repeat new monosyllables perfectly, the change that occurred in those three months must relate to something else in their phonological skills, something that is not essential to speak a language natively. Thus, we hazard the 885 hypothesis that sample differences in length effects may relate to such non-essential skills. Since

891

892

893

as stated this hypothesis is under-specified, further both conceptual and empirical work are is needed. 888

Individual variation and NWR. Our review of previous work in the Introduction 889 suggested that our anticipated sample size would not be sufficient to detect most individual 890 differences using NWR. We give a brief overview of individual difference patterns of four types in the present data—age, sex, birth order, and maternal education—hoping that these findings can contribute to future meta- or mega-analytic efforts aggregating over studies.

In broad terms, we expected that NWR scores would increase with participant age, as this 894 is the pattern observed in several of the studies in Figure ?? previous studies (English Vanceet 895 al., Stackhouse, & Wells, 2005; Italian Piazzalungaet al., Previtali, Pozzoli, Scarponi, & 896 Schindler, 2019; Cantonese Stokeset al., Wong, Fletcher, & Leonard, 2006; but note Cristiaet 897 al., not in Cristia, Farabolini, Scaff, Havron, & Stieglitz, 2020is an exception). Indeed, age was 898 significantly correlated with NWR score and also showed up as a significant predictor of NWR 899 score when included as a control factor in the analyses of both item length and average 900 segmental frequency. In brief, our results underscore the idea that phonological development continues well past the first few years of life, extending into middle childhood and perhaps later (Hazan & Barrett, 2000).

In contrast, previous work shows little evidence for effects of varies with respect to 904 correlations of NWR scores with maternal education (e.g., Farmani et al., 2018; Kalnaket al., 905 Peyrard-Janvid, Forssberg, & Sahlén, 2014; Meir & Armon-Lotem, 2017) on NWR scores. We 906 did not expect large effects of correlations with maternal education in our sample for two reasons: First, education on Rossel Island is generally highly valued and so widespread that little variation is seen there; second, formal education is not at all essential to ensuring one's success in society and may not be a reliable index of local socioeconomic variation locally. In 910 fact, maternal education correlated with NWR score at about r-...1, which is small. Similarly, 911 NWR scores may not vary greatly with participant gender according to We find correlations of

935

938

939

about that size for participant sex, which is aligned with previous work (Chiat & Roy, 2007), and for that as well we find effects of about that size.

Last but not least Finally, we investigated whether birth order might affect correlate with 915 NWR scores, as it does with other language tasks, resulting in such that first-born children 916 showing higher scores on standardized language tests than later-born children (Havron et al., 917 2019) and adults (in a battery including verbal abilities, e.g., Barclay, 2015), presumably 918 because later-born children receive a smaller share of parental input and attention than their 919 older siblings. Given shared caregiving practices and the hamlet organization typical of Rossel 920 communities, children have many sources of adult and older child input that they encounter on a daily basis and first-born children quickly integrate with a much larger pool of both older and 922 younger children with whom they partly share caregivers. Therefore we expected that any effects of correlations with birth order on NWR would be attenuated in this context. In line with this prediction, our descriptive analysis showed a non-significant correlation between birth order and NWR score. However, the effect size was larger than that found for the other two factors 926 and it is far from negligible, at r-2.2 or Cohen's d-0.41. In fact, two large studies with 927 therefore precise estimates found effects of about d—2 (Barclay, 2015; Havron et al., 2019), 928 which would suggest the effects correlations we found are larger. We therefore believe it may 929 be worth revisiting this question with larger samples in similar child-rearing environments, to 930 further establish whether distributed child care indeed results in does not result more even 931 language outcomes for first- and later-born children. 932

NWR across languages and cultures. The fourth research area to which we wanted to contribute pertained to the use of NWR across languages and populations, as since when designing this study we wondered whether NWR was a fairculture-fair test of phonological development. Although our data cannot answer this question because we have only sampled one language and population here, we would like to spend some time discussing the integration of these results to the wider NWR literature. It is important to note at the outset that we cannot obtain a final answer because integration across studies implies not only variation in languages

950

951

952

953

954

and child-rearing settings, but also in methodological aspects including non-word length,
non-word design (e.g., the syllable and phone complexity included in the items), and task
administration, among others. Nonetheless, we feel the NWR task is prevalent enough to
warrant discussion about this, as it is done for similarly to other tasks sometimes used to
describe and compare children's language skills across populations, like the recent re-use of the
MacArthur-Bates Communicative Development Inventory to look at vocabulary acquisition
across multiple languages (Frank, Braginsky, Yurovsky, & Marchman, 2017).

At first sight, the The range of performance we observed overlapped with previously observed levels of performance. Paired with our thorough training protocol, we had interpreted the NWR scores among Yélî Dnye learners as indicating that our adaptations to NWR for this context were successful, even given a number of non-standard changes to the training phase and to the design of the stimuli. Additionally, it seemed that Yélî children showed comparable performance to others tested on a similar task, despite the many linguistic, cultural, and socioeconomic differences between this and previously tested populations, unlike the case that had been reported for the Tsimane'.

To enrich this discussion, we looked for previous studies on monolingual children with 955 normative development learning diverse languages, and entered them when they reported 956 non-word repetition scores based on whole item scoring. We entered data from 14 studies 957 (including ours), presenting data from 12 languages. Specifically, Arabic was represented by 958 Jaber-Awida (2018); Cantonese by Stokes et al. (2006); English by Vance et al. (2005); Italian 959 by Piazzalunga et al. (2019); Mandarin by Lei et al. (2011); Persian by Farmani et al. (2018); Slovak by Kapalková, Polišenská, and Vicenová (2013) and Polišenská and Kapalková (2014); Sotho by Wilsenach (2013); Spanish by Balladares et al. (2016); Swedish by Kalnak et al. (2014) and Radeborg, Barthelom, SjöBerg, and Sahlén (2006); Tsimane' by Cristia et al. 963 (Cristia, Farabolini, Scaff, Havron, & Stieglitz, 2020); and Yélî Dnye from the present study. 964 Studies varied in the length of non-words that were considered; whenever results were reported 965

separately for different lengths, we calculated overall averages based on lengths of 2 and 3
syllables, for increased comparability. Results separating different age groups are shown in
Figure ??...

NWR scores as a function of age (in years), averaged across multiple non-word lengths, as
a function of children's native languages. The legend indicates language and the length of
non-words (in syllables). Central tendency is mean; error is one standard error.

Several observations can be drawn from this figure. To begin with, we focus on the 972 comparison between Yélî Dnye and Tsimane'. These two groups have been described as having 973 roughly similar levels of child-directed speech, yet they exhibit very different results: Tsimane' 974 shows lower overall NWR scores (and according to Figure ??, larger length effects). This 975 suggests that the lower NWR scores found among the Tsimane' are due to long-term effects of 976 lower levels of child-directed speech. Naturally, there is an alternative interpretation, namely 977 that input estimation suggesting very slightly higher levels of child-directed speech among the 978 Tsimane' than among Yélî Dnye learners is inaccurate. In fact, careful reading of previous 979 reports highlight important methodological differences in how input quantity has been estimated 980 across papers: Casillas et al. (2020) hand-coded speech with the help of a native research 981 assistant, and then summed all child-directed speech, which effectively establishes an upper 982 boundary of the speech children could potentially process. Cristia, Dupoux, Gurven, and 983 Stieglitz (2019) estimated quantities from behavioral observations on the frequency of 984 ehild-directed one-on-one conversation, which is probably closer to a lower boundary. Finally, Scaff et al. (2021) used human annotation for detecting speech but an automated temporal 986 method for assigning speech as child-directed or not, in a way that could lead to over-estimation (because any speech by e.g. a female adult that was not temporally close to speech by others 988 would count as child-directed). A final answer to the question of how much child-directed 989 speech is afforded to Yélî and Tsimane' children must await fully comparable methods. 990

That said, Cristia et al. (2020) also pointed out another characteristic of the Tsimane' 991 population, and this was the relatively low prevalence of literacy, and generally the variable 992 access to formal education. This is a very different case from the Yélî population studied here, 993 where nearly all adults have accumulated several years of schooling, and basic literacy in 994 English (and sometimes Yélî Dnye) is widespread. If this second hypothesis holds, then this 995 may mean that there are phonetic effects of learning to read in the input afforded to young 996 children, and that this has consequences for young children's encoding and decoding of sounds 997 in the context of NWR tasks. Notice that this is not the same as the oft-recorded effect of 998 learning to read affecting NWR performance, illustrated for instance in the data for Sotho in ggc Figure ??. These two data points have been gathered from two groups of children, all exposed 1000 mainly to Sotho, but children with higher NWR had been learning to read in Sotho, whereas 1001 those with lower scores were learning to read in English. What is at stake in our proposed 1002 alternative interpretation of the lower scores observed among the Tsimane' is related to literacy 1003 in the broader population (rather than in the tested children themselves). 1004

Although exciting, this hypothesis is only one of many. Another plausible explanation is that the Tsimane' results are not comparable to the previous body of literature, and specifically to our study. Cristia et al. (2020) administered the NWR in the form of a group game played outside, with a non-native experimenter providing the target, and each person of the group attempting it in their stead. This immediately means a number of important methodological differences with the standard implementation of NWR, where children are tested individually, they hear items spoken by a native speaker (often over headphones), the experimenter tends to belong to the same community as the children, and testing occurs in quiet conditions (with little background noise). Thus, a priority is for additional data gathered using this more novel testing paradigm in other populations, or from the Tsimane' using the more traditional paradigm.

Broadening our discussion to all of the studies in our literature review, we notice that there is rather wide variation of the range of NWR scores found across these samples, and that,

in fact, the strength of age effects also varies. We performed some exploratory analyses to see 1017 whether features of the languages children were learning could be related to their overall NWR 1018 scores. We extracted the number of phonemes in the language from PHOIBLE and coded 1019 whether words in the language tended to be longer or shorter based on information in the papers 1020 or other sources. Neither of these two predictors explained variance in Figure ??. It is possible 1021 that average word length plays a role, but often researchers incorporate this into their design by 1022 including longer items when the native language allows this, with e.g. Sotho non-words having 1023 4-7 syllables in length. To be more certain whether language Comparison across published 1024 studies is difficult (see SM2 for our preliminary attempt). To be certain whether 1025 language-specific characteristics do account for meaningful variation in NWR scores, it will be 1026 necessary to design NWR tasks that are cross-linguistically valid. We believe this will be 1027 exceedingly difficult (or perhaps impossible), since it would entail defining a 10-20 set of items 1028 that are meaningless, but phonotactically legal, in all of the languages as well as phonotactically 1029 legal. An alternative may be to find ways to regress out some of these effects differences, and 1030 thus compare languages while controlling for choices of phonemes, syllable structure, and 1031 overall length of the NWR items. As for different Both of these issues are discussed in Chiat 1032 (2015). As for the variable strengths of age effects correlations discussed above, here as well we 1033 are uncertain to what they may be due, but we do hope that these intriguing observations will 1034 lead others to collect and share NWR data. 1035

Limitations. Before closing, we would like to point out some salient limitations of the 1036 current work. To begin with, we only employed one set of non-words, in which not all 1037 characteristics that previous work suggest matter were manipulated (Chiat, 2015). As a result, 1038 we only have a rather whole-sale measure of performance, and we do not know to what extent 1039 lexical knowledge, pure phonological knowledge, and working memory, among others, 1040 contribute to children's performance. Similarly, our items varied systematically in length and 1041 typological frequency of the sounds included, but not in other potential dimensions (such as 1042 whether the items contained morphemes of the language or not). 1043

We relied on a single resource, PHOIBLE, for our estimation of typological frequency, 1044 and some readers may be worried about the effects of this choice. As far as we know, PHOIBLE 1045 is the most extensive archive of phonological inventories, so it is a reasonable choice in the 1046 current context. However, one may want to calculate typological frequency not by trying to 1047 have as many languages represented as possible, but rather by selecting a sample of 1048 typologically independent languages. In addition, it is not the case that all the world's languages 1049 are represented, and indeed some of the Yélî sounds were not found in PHOIBLE. 1050 PHOIBLE—as well as our own work—depends on phonological descriptions from linguists who 1051 are in many cases not native speakers of the languages. Because the phones in our items have 1052 largely been evidenced as phonemic via multiple analyses (i.e., minimal contrast, phonological, 1053 phonetic, and ultrasound, see Levinson, 2021), we are not concerned that changes to the 1054 phonological description in the future (e.g., if a segment loses its phonemic status) will 1055 significantly change the results presented here. Relatedly, any converging evidence from the 1056 other ongoing studies of Yélî Dnye phonological development and fine-grained analyses of 1057 sound substitutions would certainly help bolster the claims we made here. While all these 1058 limitations should be borne in mind, it is important to also consider what our conclusions were, 1059 and that is that there is a non-trivial correlation between NWR and typological frequency. At 1060 present, we do not see how imbalance in the typological selection and missing data can conspire 1061 to produce the correlation we observe. If anything, these factors should increase noise in the 1062 typological frequency estimation, in which case the correlation size we uncover is an 1063 underestimation of the true correlation. 1064

Additionally, we only had a single person interacting with children as well as interpreting children's production, so we do not know to what extent our findings generalize to other experimenters and research assistants. Furthermore, since both stimuli presentation and production data collected were audio-only, neither the children nor our research assistant were able to integrate visual cues in their interpretation. Although we know from other work that adults' perceptual performance on these types of sounds is well above chance from audio-only

presentation [REF], language processing for the majority of children will be audiovisual in natural conditions, and thus it may be interesting in the future to capture this aspect of speech. While NWR can, in theory, be used to test a variety of questions about phonological development in any language, previous work has been primarily limited to a handful of related languagesspoken in urban, industrialized contexts. The present study shows that , not only can NWR be adapted for very different populations than have previously been tested, but that effects of. In addition, we observed strong correlations with age and typological frequencymay strongly influence phonological development across these diverse settings, while effects of, while correlations with item length, participant gendersex, maternal education, and birth order, may either have little impact on this facet of language development or have an impact that varies were weaker. A consideration of previous work led us to suggest that the statistical strength of all of these effects may vary depending on the linguistic, cultural, and socio-demographic properties of the population under study. Because these latter predictors strongly relate to other language outcomes, the, in conjunction with characteristics of the non-word items used. The present findings raise many questions, including: Why do NWR scores would pattern differently across samples? What does that tell us about the relationship between lexical development, phonological development, and the input environment? What is implied about the joint applicability of these outcome measures as a diagnostic indicator for

future work, we take the present findings as robustly supporting the idea that phonological
development continues well past early childhood and as yielding preliminary support for a
potential association between individual learners' NWR and much broader patterns of
cross-linguistic phone frequency.

language delays and disorders? While answers to these questions are sought should be sought in
